different String functions and tests them on user-defined Strings.

1. `s.length()`--Measures the length of string `s`
2. `s.equals(otherString)` is a boolean that determines if `s` is equal to `otherString`
3. `s.substring(startIndex, endIndex)` method accepts a start index and an end index on `s` and prints out the resulting substring
4. `s.trim()` removes leading and trailing whitespaces (tabs, spaces)
5. `s.indexOf(subString)` finds the index where the first subString occurrence starts on `s`. If subString is not found in `s`, then the method prints -1
6. `s.lastIndexOf(subString)` finds at what index is the last occurrence of subString on `s`. If subString is not found in `s`, then the method prints -1
7. `s.charAt(index)` accepts an index and returns the character at that index (assuming that the index does not go out of bounds of `s`).

My Chosen Methods

8. `s.toUpperCase()` capitalizes all the lowercase characters of string `s` using the default locale. If `s` already has some capitilized letters, these letters stay unaffected; in other words, the method will not change these upper case characters into lower case. Also, characters that are not letters, such as numbers, dashes, etc), then these non-alpha characters will also stay unaffected
9. `s.toLowerCase()` lowercases all the uppercase characters of string `s` using the default locale. If `s` already has some lowercase letteres, these letters stay unaffected; in other words, the method will not change these lowercase letters into upper case. Also, characters that are not letters, such as numbers, dashes, etc), then these non-alpha characters will also stay unaffected
